09.4 - File Analysis

Write a program that processes the two provided text files (python_1.txt and python_2.txt) and produces the following output files.

- 1. python_1_word_frequency.txt This file should contain all of the unique words in the file python_1.txt printed one per line in alphabetical order. Each word should be followed by a colon, a space, and the number of times that word appears in python_1.txt.
- 2. python_2_word_frequency.txt This file should contain all of the unique words in the file python_2.txt printed one per line in alphabetical order. Each word should be followed by a colon, a space, and the number of times that word appears in python_2.txt.
- 3. common_words.txt This output file should contain all of the words that appear in both python_1.txt and python_2.txt, printed one per line in alphabetical order.
- 4. eitherbutnotboth.txt This file should contain all of the words that appear in either python_1.txt or python_2.txt but no words that appear in both. The words should be printed one per line in alphabetical order.

For comparison purposes, all the words should be converted to lower case and all leading and trailing punctuation should be removed. This first five lines in each of the output files is shown in Figure 1. Save your program as file_analysis_login.py, where login is your Purdue login. Then submit it along with a screenshot showing the first few lines of **all 4** output files.

```
Editor - python_1_word_frequency.txt

1 a: 5
2 able: 1
3 about: 1
4 additional: 1
5 after: 1

Editor - python_2_word_frequency.txt

1 1: 1
2 a: 21
3 allows: 1
4 also: 1
5 an: 1

(b)
```

Figure 1: The first five lines of output files (a) python_1_word_frequency.txt, (b) python_2_word_frequency.txt, (c) common_words.txt, and (d) eitherbutnotboth.txt.

Hints:

- The string module includes a punctuation string which contains all of the ASCII punctuation characters.
- It might be helpful to write a function that accepts a filename as an argument and returns a list of all the words in that file. Then have another function that accepts a list of words as an argument and returns a dictionary with the unique words in the list as keys and the number of times each word appears in the file as values.
- You can use the sorted() function to get a sorted list of the keys and values in a dictionary.
- You can use the set() function to create a set from the keys in a dictionary.
